ELECTRIC DRIVES

FOR EVERY DEMAND

Transportation

Machine and plant engineering

Steel and rolling mills

Cement and mining industry

Shipbuilding

Chemical, oil and gas industry

Water management

Renewable energy

Power plant technology

There are currently around 30 million electric machines bearing the VEM badge in use around the world. They are found aboard ships, in trains and trams, and in chemical plants and rolling mills. VEM generators produce electricity in hydropower plants and wind farms.

The VEM product range embraces variable-speed electric drive systems, special motors and special machines for outputs ranging from 0.06 kW to 42 MW, as well as a diversity of drive technology and power generation components.

Introduction

This catalogue supplies information which must be observed when selecting motors and inverters. With the aid of this information, it is possible to modify not only the mechanical, but also the electrical components of motors for inverter-fed operation. The interactions of the components

inverter, motor cable and motor, and likewise the influences of particular options, must be known. Inappropriate selections when planning a drive system usually only become evident after they result in winding and/or bearing damage.

Principal components of a drive system

A variable-speed drive system comprises the following components (see Fig. 1):

- **Incoming power supply** (line fuses, main switch, supply contactor, etc.)
- **Input components** (interference suppression filters, line reactors, etc.)
- **Inverter** (including options, e.g. brake module)
- **Output components** (reactors, dU/dt or sine-wave filters, etc.)

- **Motor cable** (important: length, type, routing, shielding, etc.)

- **Motor** (standard or special insulation, insulated bearings, etc.)

Careful specification of the individual components guarantees a long service life for the drive system and reliable compliance with the applicable regulations on EMC and mains pollution, as well as energy efficiency and an optimum price-performance ratio.

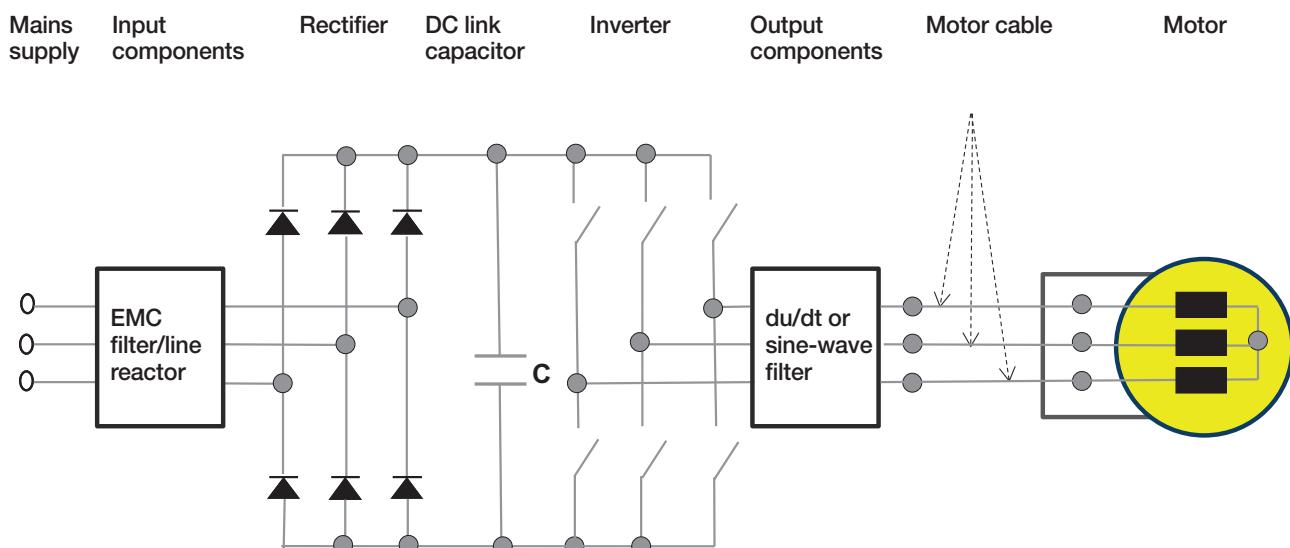

Fig. 1: Principal components of a drive system

Output and torque

In inverter-fed operation, the operating speed of the working machine can deviate from the 50 or 60 Hz rated speed of the motor. In such cases, the optimum number of poles must be determined and the power rating must be calculated or checked.

Information on the working machine and the technological process is imperative for optimum drive specification. It must be known whether a fluid machine or some other kind of machinery, e.g. conveyors, cranes, etc., is to be driven.

- With fluid machines, no further information is required if the maximum frequency corresponds to the rated frequency of the motor. Motors can be selected for the 100 % operating point, together with inverters for low overloads.
- For all other working machines, a speed-torque characteristic or at least information on certain operating points within the speed setting range is useful (for examples, see Fig. 2). If high torques are required over a longer period at low motor speeds, the duration of the load or duty cycle must be specified.

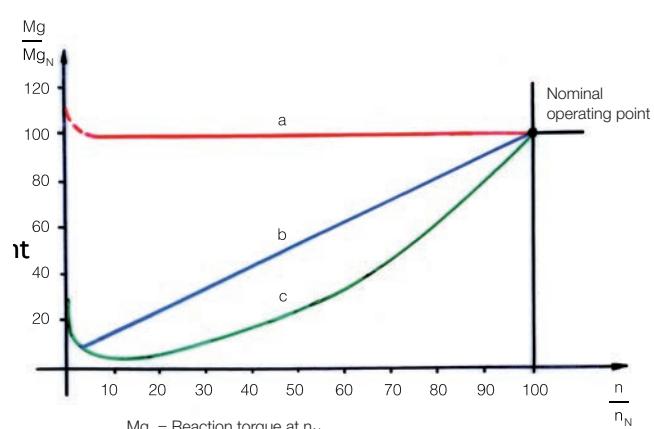

Fig. 2: Typical torque characteristics of working machines

- a. **Constant** torque over a speed range (winches, conveyors, etc.)
- b. **Linear increase in torque** with increasing speed
- c. **Quadratically increased load** torque characteristic (typical for fluid machines such as pumps and fans)

Example: 100 % operating point of a fan:

100 kW at 2400 rpm

What is the optimum number of poles for the motor?

4-pole motor:

The 100 % operating point of the fan – at 2400 rpm – lies above the rated speed of the 4-pole motor. At 2400 rpm (80 Hz), the 100 % rated output of the motor is still available (see section: Field weakening range)

At 80 Hz, however, the motor possesses only limited overload capacity. Undervoltage at the motor terminals results in quadratic further reduction of the overload capacity. This must be placed in relation to the quadratically increasing torque of the fan with increasing speed. Speed changes thus result in cubic output changes. As an increased power demand can never be fully excluded in practical operation, a reserve of 10 – 15 % should be planned for variable-speed motors which drive fluid machines. A further reserve of approx. 5 % is recommended to allow for the lower terminal voltage compared to the rated voltage of the motor, which means that a motor with an output of at least 120 kW should be selected. The appropriate choice is thus a 4-pole motor with a power rating of 132 kW.

If the motor operates above the rated frequency, it is possible to extend the range of constant torque by selecting a special winding. The output can thus be increased from 110 kW at 50 Hz to 132 kW at 60 Hz.

It is possible to use both a 4-pole 132 kW motor with 50 Hz standard winding and a 4-pole 132 kW motor with 60 Hz special winding. The latter possesses a lower mass and displays a higher overload capacity due to its lower field weakening.

2-pole motor:

To be able to calculate the output for a 2-pole motor, it is first necessary to determine the required torque M of the working machine.

$$M \text{ [Nm]} = \frac{P \text{ [kW]} \cdot 9550}{n \text{ [rpm]}} \quad 398 \text{ Nm} = \frac{100 \text{ kW} \cdot 9550}{2400 \text{ rpm}}$$

Taking the torque M and the estimated rated speed n, the power output P of the 2-pole motor can be calculated with:

$$P \text{ [kW]} = \frac{M \text{ [Nm]} \cdot n \text{ [rpm]}}{9550} \quad 124 \text{ kW} = \frac{398 \text{ Nm} \cdot 2975 \text{ rpm}}{9550}$$

This produces a power rating of 132 kW for the 2-pole motor.

Recommendation for the 2-pole motor:

A 2-pole motor is the ideal choice for standard motors. In this case, it is only operated at up to 40 Hz, which has a positive effect on the overall efficiency of the drive system, the noise level and the overload capacity.

Recommendation for the 4-pole motor:

A 4-pole motor with a 60 Hz **special winding** and 60 Hz output is a good alternative to a 2-pole motor. The potential benefit of a slightly lower mass must be weighed up against the increased fan noise and the slightly higher power losses of the drive system.

The use of a 4-pole 132 kW standard motor is a less recommended alternative due to the limited overload capacity, and is at the same time more expensive.

Additional stresses placed on motors in inverter-fed operation

Thermal stresses

The additional thermal losses in inverter-fed operation result in increases of up to 15 K in the winding temperatures on the stator and rotor. In the case of 2- and 4-pole motors **without efficiency classification** (e.g. K21R series), the increased winding temperature rise may make it necessary to reduce the rated torque and thus the rated output.

With IE2 and IE3 motors, the possibly necessary output reduction must be taken into account from size 315.

Estimation of temperature rise

VEM motors are manufactured for assignment to thermal class 155 (F) as standard.

Use of IE2 and IE3 motors up to shaft height 280 in mains-fed operation

Thermal class 130 (B)

The rated output of the IE2 and IE3 motors up to shaft height 280 is also available in inverter-fed operation. With 2- and 4-pole IE2 motors, inverter-fed operation may lead to exceeding of thermal class 130 (B), such that use in accordance with thermal class 155 (F) is assumed (F/F).

F/B means that the motor was manufactured in accordance with thermal class 155 (F), but the temperature

rise remains within the limits specified for thermal class B (maximum temperature rise 80 K).

F/F means that the motor was manufactured in accordance with thermal class 155 (F) and that the temperature rise in use also corresponds to thermal class F (maximum temperature rise 105 K).

To avoid unnecessary overdimensioning, it is expedient to refer the specification F/B to the required torque and output of the working machine rather than the rated output of the motor.

Motor voltage and winding specification

With motors intended for inverter-fed operation, a **star connection** is the preferred operating connection.

The inverters can be connected to mains power supplies with a wide voltage range (see section "Mains voltage ranges") and generally produce an output voltage which is lower than the mains voltage (with an uncontrolled input current inverter). Components such as line reactors, output filters, cables etc. lead to further voltage losses. For this reason, inverter-fed motors should be planned with a special winding for a voltage less than the nominal mains voltage as a means to compensate mains undervoltages. That is especially recommended where working machines utilise

the full rated output of the motors. Mains overvoltages are compensated by the inverter itself and pose no threat to the motor and its insulation system.

When the drive is commissioned, the inverter must be parameterised with the motor data. Tolerance specifications for the voltage and frequency, input voltage range, Zone A, Zone B, etc. are not taken into account. After parameterisation with the rating data, the motor will be fed optimally.

Example:

Mains voltage:	415 V +10 %/-15 %
Lowest mains undervoltage:	415 V -15%: ≈ 353 V
Estimated lowest voltage at the motor terminals:	approx. 342 V
Motor winding specification: 342 V/0.95: 360 V Y (star)	

It is recommended to divide the estimated lowest voltage at the motor terminals by 0.95 in order to determine the motor voltage when the standard tolerance of ± 5 % is applied. The standard tolerance is not specified explicitly and thus not marked on the rating plate.

In this case, a 360 V Y special winding is only meaningful if the power demand of the working machine is greater than 85 % of the rated motor output. If the voltage at the motor terminals lies within the normal range of ± 5 %, the thermal

reserves of the motor will generally be sufficient for continuous operation at rated output.

If, on the other hand, a motor with a 415 V Y, 50 Hz winding is used, the inverter must be parameterised with the 415 V rating data. If the mains voltage drops to 360 V during operation, the start of the field weakening range is shifted from 50 Hz to 43 Hz. The motor current increases with a constant increase in torque, which may lead to thermal overloading of the motor and possibly also the inverter. The upper frequency limit of the range of constant output is shifted to a lower frequency (see also Fig. 4).

Sine-wave filter

Due to the voltage drop of approx. 25 V, the winding voltage for a motor fed via a sine-wave filter must similarly be reduced compared to the mains voltage.

Note:

In some cases, it may well be expedient to forego voltage adaptation (i.e. specification of a special winding) for inverter-fed motors. This is possible with motor sizes ≤ 280, if a IE2 or IE3 motor is used and if, in case of doubt, the motor with the next higher power rating is chosen. For non-stock motors, the special winding will represent the more cost-effective solution.

Speed-torque characteristics

Range of constant flux (constant pull-out torque)

It is possible to set a constant flux for inverter-fed motors over the frequency range up to 50 Hz or 60 Hz. Where the motor flux is constant, the maximum (pull-out) torque is likewise constant. On the basis that the ratio U/f remains constant, the voltage rise V/Hz (1 Hz = 1 s⁻¹) and thus the voltage at any given frequency within the range of constant flux can be determined.

Example:

Motor winding (global standard voltage):	400 V/50 Hz
Nominal mains voltage (acc. to NEMA):	480 V/60 Hz
Effective voltage (acc. to NEMA):	460 V +/-10 %/60 Hz

$$400 \text{ V}/50 \text{ s}^{-1} = 8 \text{ V/s}$$

$$460 \text{ V}/8 \text{ V/s} = 57.5 \text{ s}^{-1} = 57.5 \text{ Hz}$$

The 400 V, 50 Hz motor can be operated both at 400 V/50 Hz with rated output and at 460 V with 57.5 Hz and 115 % rated output when fed via a inverter connected to a 480 V mains supply. The field weakening range begins either at 50 Hz or else only at 57.5 Hz, depending on the parameterisation. Thanks to their thermal reserves, most motors are able to deliver the 60 Hz output, i.e. 120 % rated output, at 60 Hz (460 V).

The 400 V motor can also be operated at 95 % rated output on a 380 V mains supply. As 47.5 Hz lies within the range of constant flux for a 50 Hz motor, the inverter parameterisation deviates from the rating plate data (380 V; 47.5 Hz; 0.95 x rated output, rated current and $\cos\phi$ as per rating plate).

The new speed is the synchronous speed minus the rated slip speed.

Synchronous speed:

$$n_s = \frac{f \cdot 120}{p} \quad [p - \text{pole number } (2, 4, 6, 8 \dots)]$$

$$\text{Rated slip speed: } n_{\text{slip}} = n_s - n_N$$

$$\text{Speed at new frequency: } n_{\text{new}} = n_s - n_{\text{slip}}$$

This approximate calculation of the new speed parameter can be used for frequencies to around 40 Hz.

Important:

If the nominal mains voltage lies above the rated motor voltage, the insulation system must be selected according to the higher mains voltage and not the rated voltage of the motor (taking into account the chosen output connection design).

High continuous torque in the low frequency range

The speed setting range in inverter-fed operation permits self-ventilated motors to be operated at frequencies down to 20 Hz without reducing the rated torque. Typical torque characteristics are shown in Fig. 3.

Increased torque can also be realised without forced ventilation at lower frequencies in either of the following ways:

- Use of a self-ventilated motor with the next higher power rating
- Use of a motor whose thermal capacities are utilised to a lesser extent, e.g. an IE3 motor

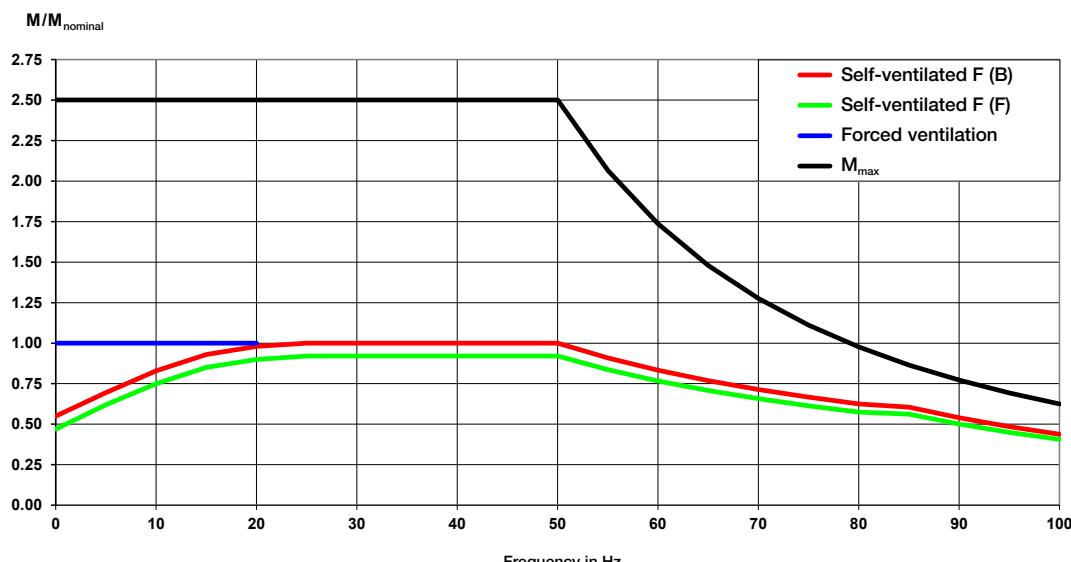

Fig. 3: General thermal limit characteristics of squirrel-cage motors with self- and forced ventilation in operation according to thermal classes B and F, plotted alongside the M_{\max} (pull-out torque) characteristic

General note:

There are no thermal reasons for forced ventilation when driving fluid machines such as pumps and fans. Forced ventilation may nevertheless be appropriate to reduce the noise level at motor speeds above the rated speed.

Field weakening range

Motors which are operated above the rated frequency with constant voltage ($U = \text{constant}$) are working in the field weakening range.

In the field weakening range, the maximum motor torque drops quadratically with increasing frequency.

The field weakening range can be divided into two sections, with the transition frequency between the two being dependent on the pull-out torque of the motor at the rated operating point.

1. Range of constant output ($P = \text{constant}$) → from $f > 50 \text{ Hz}$; from $f > 60 \text{ Hz}$, the available continuous torque drops linearly with increasing frequency

2. Range of linearly decreasing output →

Due to the quadratically decreasing pull-out torque in the field weakening range, the available torque also decreases quadratically from a frequency dependent on the pull-out torque of the motor at the rated operating point, with the result that the output drops linearly with increasing frequency.

The maximum torque (pull-out torque) in the field weakening range can be calculated as follows:

$$M_{\max} = \left(\frac{f_{\text{transition}}}{f_{\text{operating}}} \right)^2 \times M_{\text{pull-out}}$$

$f_{\text{transition}}$ – Frequency at which the field weakening range begins

$f_{\text{operating}}$ – Frequency in the field weakening range (above the transition frequency)

$M_{\text{pull-out}}$ – Pull-out torque of the motor at rated voltage and frequency

Note:

- a. To guarantee reliable operation of the motor, a reserve of at least 30% must be observed between the maximum motor torque (pull-out torque) and the required torque of the working machine.

$$M_{\text{working machine}} \leq M_{\max} \times 0.7$$

For a 50 Hz motor with a relative pull-out torque of 2.5, the range of constant output ends at approx. 85 Hz (see Fig. 3).

The maximum motor torque and the required torque of the working machine can be calculated as follows:

Maximum motor torque (pull-out torque) in the field weakening range:

$$M_{\max} = \left(\frac{f_{\text{transition}}}{f_{\text{operating}}} \right)^2 \times M_{\text{pull-out}}$$

$$\text{Required torque: } M_{\text{working machine}} [\text{Nm}] = \frac{P [\text{kW}] \cdot 9550}{n [\text{rpm}]}$$

- b. In various circumstances, the field weakening range may already begin below the rated frequency of the motor. This is always true, for example, where a voltage of only 360 V is present at the terminals of a 400 V/50 Hz motor connected behind an output filter or with long cables. In this case, field weakening already begins from 45 Hz (see Fig. 4). The range of constant output ends at approx. 80 Hz.

For drive applications where premature field weakening and the consequently higher thermal stress must be avoided, the following solutions are possible:

→ For stock motors with standard winding 230/400 V D/Y, 50 Hz

Select a motor with a higher power rating

→ For non-stock motors

Use a motor with special winding, e.g. 360 V Y, 50 Hz

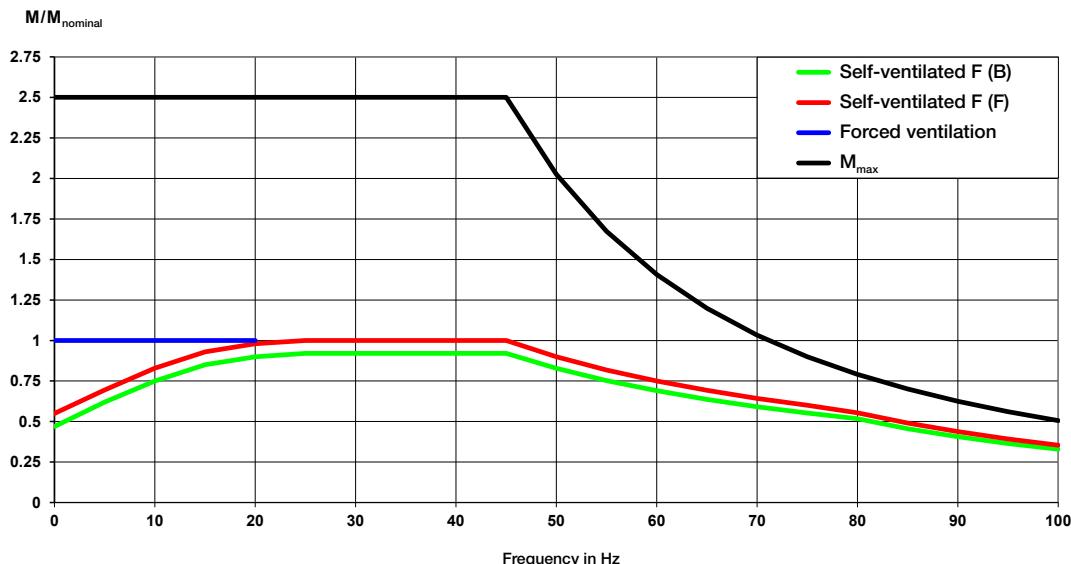

Fig. 4: General thermal limit characteristics of squirrel-cage motors with self- and forced ventilation in operation according to thermal classes B and F, plotted alongside the pull-out torque characteristic taking into account a 10 % voltage reduction at the motor terminals

Special variant of 87 Hz operation

The special variant of 87 Hz operation describes a possibility to raise the output of a inverter-fed motor. Where the rating plate of a squirrel-cage motor specifies two voltages which differ from each other by the factor $\sqrt{3}$, the lower voltage applies for delta connection of the motor, the higher voltage for star connection. If the maximum output voltage of the inverter corresponds to the higher rating plate voltage (star connection), the motor can also be operated in delta connection (Δ) if the output frequency is similarly raised by the factor $\sqrt{3}$ from 50 Hz to 87 Hz.

Example: Mains voltage: 400 V, 50 Hz
Marking of motor: 230/400 V Δ/Y , 50 Hz

Motor connection variants

- Three-phase mains supply 400 V, 50 Hz: Y
- Inverter on 400 V mains: Y → Parameterisation: 400 V, 50 Hz
- Three-phase mains supply 230 V, 50 Hz: Δ
- Inverter on 400 V mains: Δ → Parameterisation: 400 V, 87 Hz

It was already mentioned in the section “Motor voltage and winding specification” that star connection is the preferred configuration for the operation of inverter-fed motors. The special variant of 87 Hz operation consciously foregoes the benefits of this connection for inverter-fed operation.

It can be seen from Fig. 5 that the rated torque ($M/M_{\text{nominal}} = 1.00$) of a motor in the output class $> 7.5 \text{ kW}$ will not usually be available in continuous operation at 87 Hz. Depending on the motor size and specification, it must be reduced by up to 18 % in continuous operation.

Benefits of 87 Hz operation:

- Increased speed raises the continuous output of motors $\leq 7.5 \text{ kW}$ by the factor $\sqrt{3}$
- Speed setting range extended by the factor $\sqrt{3}$ with constant torque
- Reduced mass moment of inertia of the rotor

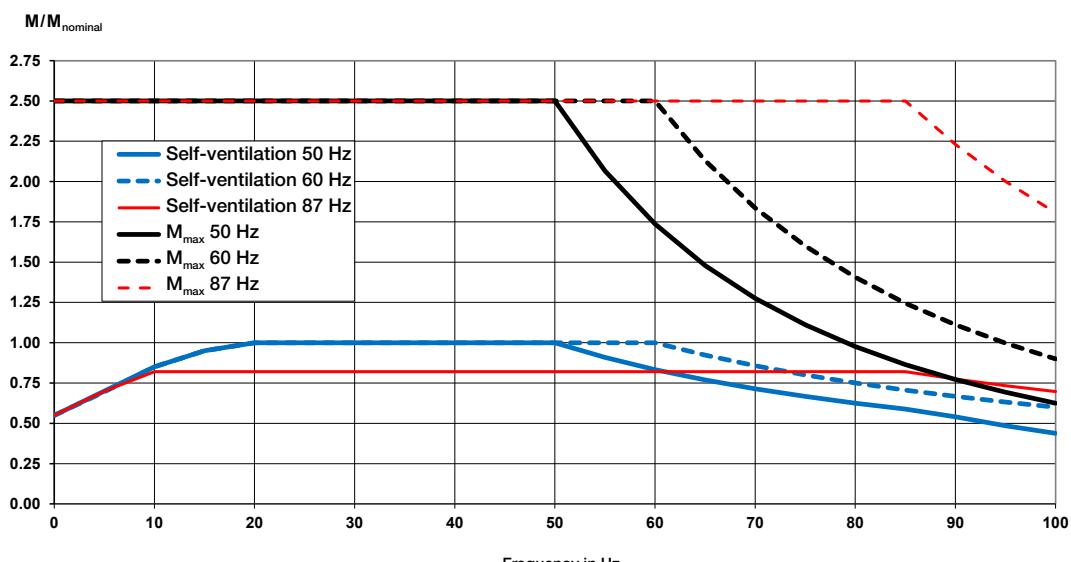

Fig. 5: General thermal limit characteristics of self-ventilated squirrel-cage motors ($> 7.5 \text{ kW}$) for 50 Hz, 60 Hz and 87 Hz, plotted alongside the corresponding M_{max} (pull-out torque) characteristics

The following side effects must be taken into account in 87 Hz operation:

- The delta connection subjects the winding insulation to very high voltage stresses
- Disproportionately increased additional motor losses, as a result of which it may be necessary to reduce the rated torque at the 87 Hz operating point by up to 18 %
- Disproportionately increased fan losses
- Increased fan noise (possibly necessitating forced ventilation)
- High bearing stresses (possibly necessitating a relubrication system).
- It may be necessary to use a larger inverter

Notes with regard to the pole numbers and outputs of motors suitable for 87 Hz operation in the standard version:

- 2-pole: Up to 30 kW at 50 Hz (approx. 42 kW at 87 Hz)
Limitation: Maximum speed of the standard motor
- 4-pole: Up to 55 kW at 50 Hz (approx. 77 kW at 87 Hz)
Dependent on the drive application; a 2-pole motor may be more suitable. Options such as a larger terminal board and larger terminal box, as well as relubrication system, forced ventilation, etc., may be necessary.
- 6-pole: Not meaningful (use instead a 4-pole motor, possibly with 60 Hz special winding)
- 8-pole: Not meaningful and not economical (depending on the application, use instead a 4-pole standard motor or 6-pole motor with 60 Hz special winding)

Voltage stresses (insulation systems)

Table 1 shows the insulation systems used by VEM, the maximum permissible pulse voltages \hat{U}_{LL} and the application possibilities for different mains voltages. The prerequisite where motors are operated without filter at the inverter output is star connection of the windings. Furthermore, the following applies for the different application possibilities:

- x → For inverters with uncontrolled input rectifier
→ No limitations
- 1 → No regenerative/braking operation
- 2 → No regenerative/braking operation, no use in complex drive systems with central DC link, no voltage boosting with controlled input inverter
- → Motor operation not permissible without filter at the inverter output

Types/series	Standard series		KU.R, KU.-F, WU.R, WU.F		KV.R, KV.F
Insulation system	to Sp2945	Standard	Reinforced KU		Reinforced KV
Sizes	BG ≤ 132 *)	BG ≥ 132 *)	BG ≤ 132 *)	BG ≥ 132 *)	BG ≥ 132
Pulse voltage \hat{U}_{LL}	1350 V		1560 V	1800 V	2500 V
Mains voltages					
up to 400 V	x		x		x
up to 440 V	1		x		x
up to 500 V	2		2	x	x
up to 600 V	-		-	2	x
up to 690 V	-		-		x

Table 1: VEM insulation systems for inverter-fed motors

*) see section: Options/Motors

Correlations with regard to voltage stresses at the motor terminals:

- Short motor cable → high rate of voltage rise (dU/dt)
→ low peak voltage \hat{U}_{LL}
- Long motor cable → low rate of voltage rise (dU/dt)
→ high peak voltage \hat{U}_{LL}

The maximum motor cable length is dependent on the inverter output, the voltage level and the cable design (shielded/unshielded). The maximum length for a shielded motor cable is usually only approx. 2/3 of the length of a cable without shielding. As a rough guide, the following ap-

plies with regard to the motor cable length for configurations without filter at the inverter output:

- Inverter output ≤ 4 kW → short motor cable (\leq approx. 35/50 m) shielded/unshielded)
- Inverter output ≥ 22 kW → long motor cable (\geq approx. 100/150 m) shielded/unshielded)

NAMUR

“User Association for Automation Technology in the Process Industries”

In NAMUR recommendation NE 38, it is proposed that filters should always be provided at the output of a inverter as a means to

- reduce voltage stresses
- minimise harmonic effects and
- suppress electromagnetic interference.

The following values are to be considered suitable limit values:

For 400 V and 500 V motors:
 $\hat{U}_{LL} < 1000 \text{ V}$ and $dU/dt < 500 \text{ V}/\mu\text{s}$

For 690 V motors:
 $\hat{U}_{LL} < 1350 \text{ V}$ and $dU/dt < 500 \text{ V}/\mu\text{s}$

In a drive system configured to comply with **NAMUR** specifications, the motors can be designed with **standard insulation** or **insulation to Sp2945**, irrespective of the mains voltage; a filter is to be provided at the inverter output.

Bearing stresses (insulated bearings)

Insulated bearings must be used on the non-drive side of inverter-fed motors from size 315. Motors of the KU.. and KV.. series possess insulated bearings as standard from size 315.

Where motors with high pole numbers and standard insulation are used to drive fluid machines, it is sufficient to provide insulated bearings from outputs of 100 kW.

In case of frequent operation at low frequencies ($f_{mot} < 10 \text{ Hz}$) and with high torque, VEM recommends the use of insulated bearings on the non-drive side also with motors of smaller sizes.

Bearing currents can also be reduced by the following measures:

- Use of dU/dt or sine-wave filters
- Use of common mode filters
- Good RF earthing between the motor and inverter housing
- Use of symmetrical multi-core motor cables

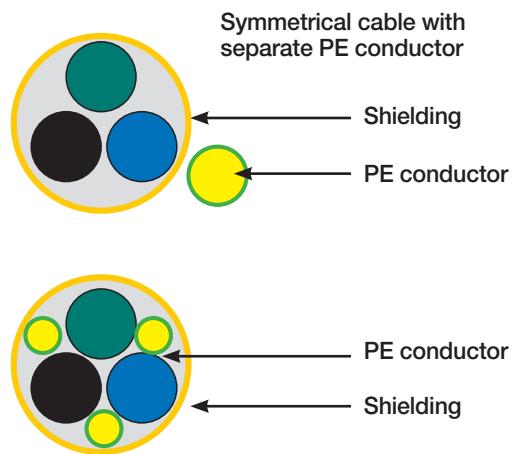

Fig. 6: Symmetrical multi-core motor cables

Information required for drive specification

For proper specification of a variable-speed drive system, at least the following information is required

- Mains voltage
- Required torque of the working machine over the speed setting range
- Duration of operation at $f < 20 \text{ Hz}$ (not for quadratically decreasing torque characteristic)

- Overload requirements and times, etc.
- Thermal reserves
- Maximum cooling air temperature, if above $+40^\circ\text{C}$
- Maximum installation altitude, if more than 1000 m above sea level

Basic data of inverters

Mains voltage ranges

Mains voltage ranges: 230 – 480 V +10 %/-15 %
 (-10 % at 230 V)
 440 – 525 V +10 %/-15 %
 (up to 74 A)
 500 – 690 V +10 %/-15 %
 (from 90 A)

Mains frequency: 45 to 65 Hz
 Power factor: 0.95

Overload capacity and degree of protection

Drives of fluid machines (quadratically increased load torque characteristic) are required to handle only minor overloading. The inverter can be operated with a higher continuous

current than is the case with drives for higher overload requirements. VEMoDRIVE inverters in the SD variant (Standard Dynamic) satisfy such requirements.

Inverters for applications with high overload requirements possess a lower continuous current. The high thermal reserves are required to handle 150 % overload current for 1 minute every 10 minutes.

Inverters are to be selected in accordance with the rated and overload currents (overload torque) rather than the output of the motor. In applications requiring only low dynamic performance where – for whatever reason – the motor must be overdimensioned, the inverter can be selected to match the actual motor current rather than the (higher) current specified on the rating plate.

Inverters can be supplied as follows:

380 – 460 V mains connection:

up to 250 A	→ wall-mounted unit, IP 20/21 or IP 54
from 300 A	→ cabinet unit, IP 54

480 – 690 V mains connection:

up to 200 A	→ wall-mounted unit, IP 20/21 or IP 54
from 250 A	→ cabinet unit, IP 54

From 300/250 A, modules can also be supplied with IP 20 protection for installation in switch cabinets.

Cooling

The inverter output currents specified in the selection tables apply for an ambient temperature of +40 °C.

Inverters with IP 54 protection may be operated at higher ambient temperatures if the current is reduced by 2.5 %/°C.

The following maximum ambient temperatures are to be observed:

Inverters up to 74 A:	max. +50 °C
Inverters from 90 A:	max. +45 °C

Switching frequency

The standard switching frequency for inverters is 3 kHz.

Generally speaking, the following applies:

- Increasing frequency (max. 6 kHz)
 - higher inverter losses
 - lower motor losses
 - reduced switching noise at the motor

– Decreasing frequency (min. 1.5 kHz)

- lower inverter losses
- higher motor losses
- increased switching noise, depending on the pulse pattern

Options

Motors

Insulation systems

a) Motor sizes ≤ 112

Mains voltage 400 V

Motors in sizes ≤ 112 must not be operated on inverters without output filter unless they have been manufactured according to special drawing Sp2945. The order must specify **Sp2945**.

Mains voltage 500 V

For non-certified standard and special motors, a reinforced insulation system is dependent on the design status of the series. This is indicated by way of a "U" after the letter "W" in the selection tables. The motors can be used for drive systems where peak voltages up to 1560 V are to be expected at the motor terminals. The insulation system is an element of the type designation and thus not an option in the proper sense.

In the case of certified motors, e.g. marine motors or motors for the North American market, the reinforced insulation system is an option indicated by the additional letters "TU".

Mains voltage 690 V:

It is not permissible to operate motors in sizes ≤ 112 without filter at the inverter output. The type of filter is dependent on the insulation system: Sine-wave filter for a withstand voltage of 1350 V or du/dt filter for a withstand voltage of 1560 V.

b) Motor size 132

Motors in size 132 can be manufactured with an insulation system corresponding to either a) or c), depending on the type. If a reinforced insulation system in accordance with c) is required, therefore, it is necessary to submit a separate enquiry.

c) Motor sizes ≥ 160

For non-certified standard and special motors in sizes ≥ 160, a reinforced insulation system is similarly dependent on the design status of the series. In the selection tables, this is indicated by way of a "U" for insulation systems up to a peak voltage of 1800 V or a "V" for insulation systems up to a peak voltage of 2500 V. For these motors, the insulation system is an element of the type designation and thus not an option in the proper sense.

In the case of certified motors, e.g. marine motors or motors for the North American market, the reinforced insulation system is an option indicated by the additional letters "TU" for a withstand voltage of 1800 V or "TV" for a withstand voltage of 2500 V.

Winding protection

VEM recommends that inverter-fed motors should always be provided with winding protection.

In the case of forced ventilation or motors which must also deliver a high continuous torque at frequencies below 20 Hz, winding protection is imperative.

Important:

Motors with reinforced winding insulation incorporate temperature sensors with enhanced dielectric strength (higher price compared to the standard version).

The following options are available as standard for winding protection:

- 3 PTC sensors (TPM) for disconnection or 2 x 3 PTC sensors for warning and disconnection
- Temperature sensor (KTY)
- Resistance thermometer Pt100 (PT)
- Microtherm switch (MT)

Insulated bearings (IL)

Criteria for use: See section "Bearing stresses (insulated bearings)"

Relubrication system (NS)

Motors in sizes from 315 MX are supplied with a relubrication system as standard. A relubrication system can be supplied as an option for motors in sizes from 132 (except 132 T) to 315 M at extra cost.

Where the operating speed of a motor lies significantly above the rated speed or else the motor is to be operated in high ambient temperatures, a relubrication system may be expedient also for smaller shaft heights.

Encoders

The following incremental encoders are standard options:

- BaumerThalheim ITD 2. up to size 80
- BaumerThalheim ITD 4. up to size 132 T
- Leine & Linde 861 from size 132

Where the motor is fitted with an insulated bearing, either an insulated encoder must be used (extra cost) or else the standard encoder must be mounted with corresponding insulation.

Forced ventilation (or water cooling)

Forced ventilation is an element of the type designation for surface-cooled motors and is thus not marked separately. Forced ventilation fans from Wistro are used as standard for all motor sizes. They are used above all where an otherwise self-ventilated motor is planned for

- operation at frequencies below 20 Hz and with high torques in continuous operation, or
- operation at speeds far in excess of the rated speed where a required maximum noise level cannot be observed with self-ventilation.

Water-cooled motors are a separate design variant and can be supplied from size 225.

Brake

A Stromag brake can be mounted on all motors specified in the selection tables. To enable verification of intended application, it is recommended to specify the required holding or braking torque in the order. If necessary, the rectifier can be installed in the terminal box.

Cable entry

On motors from size 250, the number and diameters of the cable entries must be compared with the requirements of the application. The number of cables specified in the selection tables corresponds to the number of terminal studs in the inverters. It should be noted that the recommended cable cross-section represents the permissible maximum for most high-current inverters.

Cable glands

If screwed cable glands are not specified, EMC-compliant types are to be used with inverter-fed motors.

Inverters

Standard options

Field bus and Ethernet modules

- Profibus
- DeviceNet
- Modbus/TCP
- EtherCAT
- Profinet IO 1-port
- Profinet IO 2-port

Additional boards

- I/O board
- Encoder board
- PTC/Pt100 board
- CRIO board
- RS232/RS485 isolated

Coated boards

Factory options

- External voltage supply
- Safe stop
- Brake chopper
- EMC filter class C2
- PTC

Operating units

- Handheld operating unit
- External operating unit IP 54 for mounting in a cabinet door
- Dummy plate as mounting support for external operating unit

Additional options

- Output reactors
- Sine-wave filters
- Brake resistors

Technical data/selection tables

The selection tables contain suggestions as to which motors and inverters can be combined to form a VEMoDRIVE Single drive system. The drives are grouped according to the mains voltages 400 V, 500 V and 690 V.

Motors

Insulation systems are assigned to the individual mains voltages 400 V, 500 V and 690 V.

400 V mains:	Insulation according to Sp2945 and standard insulation (\hat{U}_{LL} up to 1350 V) Operation without output filter is permissible
500 V mains:	Reinforced (KU) insulation (\hat{U}_{LL} up to 1560/1800 V) Operation without output filter is permissible
690 V mains: a)	Reinforced (KU) insulation (\hat{U}_{LL} up to 1560/1800 V) Operation only permissible with du/dt filter

b) Reinforced (KV) insulation (\hat{U}_{LL} up to 2500 V)
Operation without output filter is permissible

Kalasanati.com

The motors with standard and KU insulation are energy-saving motors with classification to efficiency class IE2. Motors with KV insulation are manufactured solely for inverter-fed operation. Due to their deviating size-output rating assignments, they are reserved for particular applications and are thus not classified.

It is also possible to supply 8-pole IE2 and IE3 motors and unclassified motors with higher numbers of poles. The available variants can be taken from the VEM Electronic Catalogue (**VEM eKAT^{V10}**).

Inverters

Each motor can be incorporated into either of two drive systems, which differ in terms of the torque characteristics of the working machine and the overload capacity of the inverter. The available inverter variants are designated Standard Dynamic (SD) and High-Dynamic (HD).

Overload capacity 120 %:

Fluid machines place no great demands on the overload capacity of the drive unit. The high degree of utilisation of the thermal capacity of the inverter permits a high continuous current. Such applications are the principal domain of inverters in the SD variant. The inverter size is determined by the rated current of the motor rather than the rated output. Thermal overloading of the motor at lower speed can usually be excluded on account of the quadratically decreasing torque characteristic of the fluid machine.

Overload 150 %:

Inverters for drives with high overload requirements must possess high thermal reserves. For this reason, it is generally necessary to use a inverter with a higher current than is the case for a fluid machine.

For simple applications, it is still possible to use a VEMoDRIVE inverter in the SD variant. Where high demands are placed on the dynamic performance of the motor and where constant torques and speeds are important, however, it is necessary to select a VEMoDRIVE inverter in the HD variant.

Important:

Not all SD inverters can be upgraded to produce an HD inverter.

Depending on the voltage level, inverters up to 250 A or 200 A are available as wall-mounted units, those for higher currents as modules (IP 20) or cabinet units.

Higher outputs than those specified in the tables can be supplied by special request.

Technical data/selection tables

with self-ventilated 2-pole energy-saving motors for normal operation (overload 120 %, 1 minute every 10 minutes)

IE2 motors (for 50 Hz mains operation) for the output range from 0.09 kW to 500 kW

IE3 motors (for 50 Hz mains operation) for the output range from 560 to 710 kW (size 400)

Mains voltage: 400 V

Motor sizes > 450 by request

All motors can be supplied with optional forced ventilation at additional cost.

The "R" (rib-cooled with self-ventilation) in the type designation is to be replaced with "F" (forced ventilation).

Technical data/selection tables

with self-ventilated 4-pole energy-saving motors, series IE2-WU.R with reinforced insulation for heavy duty (overload 150 %, 1 minute every 10 minutes)

IE2 motors (for 50 Hz mains operation) for the output range from 0.06 kW to 500 kW

IE3 motors (for 50 Hz mains operation) for the output range from 560 to 1000 kW (size 400 and 450)

Mains voltage: 500 V

Motor sizes > 355 by request

All motors can be supplied with optional forced ventilation at additional cost.

The "R" (rib-cooled with self-ventilation) in the type designation is to be replaced with "F" (forced ventilation).

depending on requirements

... 1: Standard Dynamic (SD) or

... 2: High Dynamic (HD)

Technical data/selection tables

4-pole, self-ventilated squirrel-cage motors, series KV.R, with reinforced ventilation

for applications with quadratically increased load torque characteristic (overload 120 %, 1 minute every 10 minutes) Without filter at the inverter output (maximum phase-to-phase pulse voltage: **2.5 kV**)

Mains voltage: 690 V

A = by request

Motor sizes > 355 by request

All motors can be supplied with optional forced ventilation at additional cost.

The "R" (rib-cooled with self-ventilation) in the type designation is to be replaced with "F" (forced ventilation)..

depending on requirements

... 1: Standard Dynamic (SD) or

... 2: High Dynamic (HD)
